Standard Test Method for Shear Strength of Plastics by Punch Tool

1. Scope *

1.1 This test method covers the punch-type of shear test and is intended for use in determining the shear strength of test specimens of organic plastics in the form of sheets and molded disks in thicknesses from 1.27 to 12.7 mm (0.050 to 0.500 in.).

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

Note 1—There is no known ISO equivalent to this standard.

E 691 Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method

3. Terminology

3.1 Definition:
3.1.1 shear strength—the maximum load required to shear the specimen in such a manner that the moving portion has completely cleared the stationary portion. It is expressed in megapascals (or pounds-force per square inch) based on the area of the sheared edge or edges.

4. Significance and Use

4.1 Shear strength obtained by a tool of the punch type is one of the recognized methods of comparing materials or obtaining data for engineering design. However, it must be recognized that for end-use application there may be many factors not taken into account in this test method, such as stress-concentrating geometries and rates of shear, which can profoundly affect shear strength. Moreover, the fact that the shear strength is calculated by dividing the load by the area of the sheared edge (circumference X thickness) should not be interpreted as indicating that the shear strength value so obtained is solely a material property, independent of thickness.

4.2 For many materials, there may be a specification that requires the use of this test method, but with some procedural modifications that take precedence when adhering to the specification. Therefore, it is advisable to refer to that material specification before using this test method. Table 1 of Classification System D 4000 lists the ASTM materials standards that currently exist.

5. Apparatus

5.1 Testing Machine—Any suitable testing machine of the constant-rate-of-crosshead movement type. The testing machine shall be equipped with the necessary drive mechanism for imparting to the crosshead a uniform, controlled velocity with respect to the base. The testing machine shall also be equipped with a load-indicating mechanism capable of showing the total compressive load carried by the test specimen. This mechanism shall be essentially free from inertia-lag at the specified rate of testing and shall indicate the load with an accuracy of ±1% of the indicated value or better. The accuracy of the testing machine shall be verified in accordance with Practices E 4.

5.2 Shear Tool—A shear tool of the punch type which is so constructed that the specimen is rigidly clamped both to the stationary block and movable block so that it cannot be deflected during the test. A suitable form of shear tool is shown in Fig. 1.

---

*A Summary of Changes section appears at the end of this standard.
5.3 **Micrometers**—Suitable micrometers for measuring the thickness of the test specimen to an incremental discrimination of at least 0.025 mm (0.001 in.).

6. **Test Specimen**

6.1 The specimen shall consist of a 50-mm (2-in.) square or a 50-mm (2-in.) diameter disk cut from sheet material or molded into this form. The thickness of the specimen may be from 1.27 to 12.7 mm (0.050 to 0.500 in.). The upper and lower surfaces shall be parallel to each other and reasonably flat. A hole approximately 11 mm (7/16 in.) in diameter shall be drilled through the specimen at its center.

7. **Conditioning**

7.1 **Conditioning**—Condition the test specimens at 23 ± 2°C (73.4 ± 3.6°F) and 50 ± 5% relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618 unless otherwise specified by contract or the relevant ASTM material specification. Reference pre-test conditioning, to settle disagreements, shall apply tolerances of ±1°C (1.8°F) and ±2% relative humidity.

7.2 **Test Conditions**—Condition the test specimens at 23 ± 2°C (73.4 ± 3.6°F) and 50 ± 5% relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618 unless otherwise specified by contract or the relevant ASTM material specification. Reference pre-test conditioning, to settle disagreements, shall apply tolerances of ±1°C (1.8°F) and ±2% relative humidity.

8. **Procedure**

8.1 Use five specimens.

8.2 Measure the thickness of the test specimen with a suitable micrometer to the nearest 0.025 mm (0.001 in.) at several points 12.7 mm (0.500 in.) from its center.

8.3 Place the specimen over the 9.5-mm (3/8-in.) pin of the punch and fasten tightly to it by means of the washer and nut. Then assemble the tool jig and tighten the bolts.

8.4 Maintain the crosshead speed of the machine during the test at 1.25 mm (0.05 in.)/min, measured when the machine is running idle. The tolerances should be 1.3 ± 0.3 mm (0.050 ± 0.010 in.)/min.
8.5 Push down the punch far enough so that the shoulder clears the specimen proper. The specimen will then be adjacent to the necked-down portion of the punch, and it should be possible to remove the specimen readily from the tool.

**Note 2**—For thick specimens of some materials the punched-out piece tends to stick in the die. If the test is continued only to the point where maximum load has been developed and starts to fall off rapidly, the specimen may be readily removed from both punch and die.

9. Calculation

9.1 Calculate shear strength in megapascals (or pounds-force per square inch), determined by dividing the load required to shear the specimen by the area of the sheared edge, which shall be taken as the product of the thickness of the specimen by the circumference of the punch.

10. Report

10.1 Report the following information:

10.1.1 Complete identification of the material tested, including type, source, manufacturer’s code number, form, principal dimensions, previous history, etc.,

10.1.2 Method of test, type of test specimen, and dimensions,

10.1.3 Atmospheric conditions in the test room,

10.1.4 Conditioning procedure used,

10.1.5 Diameter of punch,

10.1.6 Load in newtons (or pounds-force) required to shear each specimen, and the average value, and

10.1.7 Shear strength in megapascals (or pounds-force per square inch) for each specimen, the average value, and the standard deviation.

11. Precision and Bias

11.1 Table 1 is based on a round-robin test conducted in 1983, in accordance with Practice E 691, involving six materials tested by eleven laboratories. Each “test result” was the average of five individual determinations. Each laboratory obtained one test result for each material.

**Note 3**—Caution: The following explanations of 

11.2 Concept of r and R in Table 1—If 

11.2.1 Repeatability—Two test results obtained within one laboratory shall be judged not equivalent if they differ by more than the 

11.2.2 Reproducibility—Two test results obtained by different laboratories shall be judged not equivalent if they differ by more than the 

11.2.3 The judgments in 11.2.1 and 11.2.2 will have an approximately 95% (0.95) probability of being correct.

11.3 Bias—No statement may be made about the bias of this test method, as there is no standard reference material or reference test method that is applicable.

12. Keywords

12.1 punch tool; shear strength

- **a** The complete designations for the materials in Table 1 are: reaction injection molding (RIM), high-density polyethylene (HDPE), sheet molding compound (SMC), and polytetrafluoroethylene (PTFE).
- **b** \(S_r\) is the within-laboratory standard deviation for the indicated material. It is obtained by pooling the within-laboratory standard deviations of the test results from all of the participating laboratories: 
  \[ S_r = \sqrt{\left(\sum S_r^2\right)/n} \]
- **c** \(S_{1r}\) is the between-laboratory reproducibility, expressed as standard deviation: 
  \[ S_{1r} = \sqrt{\left(\sum S_{1r}^2\right)/n} \]
- **d** \(r\) is the within-laboratory critical interval between two test results: 
  \[ r = 2.8 \times S_r \]
- **e** \(R\) is the between-laboratory critical interval between two test results: 
  \[ R = 2.8 \times S_{1r} \]

SUMMARY OF CHANGES

This section identifies the location of selected changes to this test method. For the convenience of the user, Committee D20 has highlighted those changes that may impact the use of this test method. This section may also include descriptions of the changes or reasons for the changes, or both.

D 732 - 02:
(1) Revised 7.1 and 7.2.

D 732 - 99:
(1) Changes to scope, ISO equivalency statement added, precision and bias statement placed in appropriate format, and keywords added.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.
